

Title	Assessment of White Gum Moist Forest on NSW Crown Forest Estate
Alternative title(s)	Indicative White Gum Moist Forest: Survey, Classification and Mapping Completed for the NSW Environment Protection Authority
Abstract	<p>An indicative map for White Gum Moist Forest (WGMF) was constructed to resolve long-standing issues surrounding its identification, location and extent within the NSW State Forest estate covered by the eastern Regional Forest Agreements. The determination of WGMF was reviewed by the project's Threatened Ecological Community (TEC) Reference Panel (the Panel), and a set of diagnostic parameters for identifying the WGMF TEC was agreed. Our mapping process relied upon the occurrence of <i>E.dunnii</i> to diagnose the presence of WGMF.</p> <p>We reviewed existing vegetation maps, predictive models and observation records of <i>E.dunnii</i> to identify State Forests that are known or likely to include stands of the species. We then attempted several different approaches to sampling and mapping <i>E.dunnii</i> using ground based surveys, predictive modelling and aerial photograph interpretation (API). We used API assessment of known <i>E.dunnii</i> stands to identify image patterns and signatures that indicated the presence of <i>E.dunnii</i>. We used our findings to examine un-surveyed areas of relevant state forests via API, and then we mapped any areas which appeared to be dominated or co-dominated by <i>E.dunnii</i>. We also developed a Random Forest presence-absence model and used it to predict the distribution of WGMF across its range. We constructed an indicative map of WGMF using the combined results of our API mapping and our predictive model. In total, we mapped approximately 980 hectares of forest likely to be dominated or co-dominated by <i>E.dunnii</i> across 16 State Forests. Two thirds of the mapped area is associated with the northern populations of <i>E.dunnii</i> – the largest areas were in Beaury, Donaldson and Yabbra State Forests. In the southern area, Kangaroo River State Forest includes the largest representation of <i>E.dunnii</i> in State Forest. Our conclusions from this exercise is that our API interpretation is capable of separating <i>E.dunnii</i> from other related eucalypts but only where it is supported by field reconnaissance. Therefore, further work is required to increase API confidence throughout its range before our maps are suitable for operational applications. Nonetheless, our indicative map is still useful for providing a list of State Forests that include mapped areas of <i>E.dunnii</i> and identifying the areas that have corroborating field based evidence of <i>E.dunnii</i>. As our indicative map stands at present, we consider that it overestimates the extent of <i>E.dunnii</i> and its dominance, however, it is unlikely that extensive stands exist outside our mapped areas. We also conclude that existing mapping (including both forest type mapping and OEH (2012) mapping) significantly underestimates the likely true extent).</p> <p>Indicative TEC Mapping have been generated from best available composite environmental data layers - standardised to 30 m pixels.</p>

Lineage	Line Work has been derived from the interpolation of Random Forest models based on the combination of 30m gridcell resolution climatic, topographic, substrate and remotely sensed variables. Individual grid cells represent probabilities of occurrence based on unique combinations and thresholds applied to selected variables. The lineage of model data has been drawn from a set of 158 individual data layers representing the NSW environmental data coverage.
