## Title Coastal Vegetation of North East NSW. VIS ID 3885

## Alternative title(s)

 $CoastVeg\_NE\_NSW\_E\_3885$ 

## **Abstract**

Fine scale vegetation mapping for areas of coastal north east NSW undertaken by Steve Griffiths and Bob Wilson from 1984 to 2012. The mapping includes all large and many smaller conservation reserves from the Forster district northwards, in addition to areas of significant native vegetation on crown or freehold land. Aerial photo interpretation (API) of predominantly 1:25000 colour photography, and limited coverage at scales of 1:10000 and 1:16000.

The structural classification follows Walker & Hopkins (1984). Subformation names are an adaptation of the classification proposed by Beadle & Costin (1952). The communities were named after dominant indicator species of the tallest stratum (and occasionally lower stratum), and most could be considered associations using the definition of Beadle (1981).

The separately mapped areas were merged into a single dataset in 1994. Yuraygir was updated in 2001-02. In 2011 three additional areas were included: Booti Booti National Park (1999), Frogalla Swamp (1996)and Saltwater Catchment (2005, Kendall and Kendall). NB. Frogalla and Saltwater were mapped for non OEH projects.

The combined dataset includes the following areas:

- Booti Booti NP
- Broadwater NP
- Bundjalung NP
- Crowdy Bay NP
- Diggers Camp VCL
- Emerald Beach VCL
- Frogalla Swamp (GTCC contract, 1996)
- Goanna Headland VCL
- Hat Head NP
- Hathead NP
- Iluka NR
- Kattang NR
- Lake Innes NR
- Limeburners Creek NR
- Minnie Waters VCL
- Moonee Beach NR
- Newrybar Swamp VCL
- Richmond River VCL
- Saltwater Catchment (DLWC contract, P.Kendall, 2003)
- Yuraygir NP

Please note that many of the reserve boundaries have expanded since the original vegetation mapping. RN17 Forest Type codes were only added to the vegetation mapping in 1994 ie. the later additions do not have FT codes in the attribute table.

Other coastal reserves mapped by Griffiths and/or Wilson that have not been included in this merged dataset are:

Khappinghat NR 2000 Wallis Island NR 2017

vegetation survey and ecological studies in Bundjalung National Park as a B.Sc. (Hons.) project with the University of New England, Armidale under the supervision of the late John B. Williams (Griffith 1983). Systematic vegetation surveys were initiated at a time when little was known about the floristic composition and spatial distribution of coastal plant communities in northern NSW, especially those representing structural formations other than forest (e.g. mallee, shrubland, heathland, sedgeland).;; S. Griffith has collaborated with API (air photo interpretation) specialist R. Wilson since inception of the project, and this partnership has produced a series of maps at scales of 1: 25000 or larger for extensive areas of vegetation along approximately 500 km of coastline in northern NSW. Apart from a hardcopy map sheet for Booti Booti National Park and several island reserves in Wallis Lake (Griffith et al. 2000), the mapping is unpublished. Nonetheless, most of the mapping has been integrated into a GIS (geographical information system) managed by the North East (Coffs Harbour) branch of the NSW Department of Environment and Climate Change. S. Griffith and R. Wilson continue their collaboration on projects to map and document coastal vegetation in northern NSW (e.g. Griffith and Wilson 2009).; ; Project methods:; ; Air photo interpretation; ; The mapping of coastal vegetation patterns in north-eastern NSW has been achieved with air photo interpretation (API) of stereo-paired photography, generally in colour at a scale of 1: 25 000. Much of the initial API was undertaken in the 1980s using comparatively crude sketch mapping techniques to transfer polygons onto 1: 25 000 CMA map bases. This work was supplemented by additional mapping in the early 1990s for the NRAC project. Digital on-screen stereo capture techniques have been used in the most recent projects. ; ; Delineation of map units; ; API groups are the basic map unit derived from stereoscopic interpretation of vegetation patterns, and these are primarily distinguished on the basis of habitat, and structure and floristic composition of the dominant (generally tallest) stratum. Each API group is assigned to a vegetation formation (e.g. forest, heathland) and subformation (e.g. swamp sclerophyll forest, dry heathland). The structural classification follows Walker and Hopkins (1984), and subformation categories are adopted or modified from the classification by Beadle and Costin (1952).; ; API groups are distinguished on vegetation maps using 5-digit numeric codes. The first four digits of each code identify the formation, subformation and floristic assemblage. For example, codes in the series 0000-4999 are assigned to forest and woodland, those in the series 4000-4499 are assigned to swamp sclerophyll forest and woodland, and swamp sclerophyll forest or woodland with a tallest stratum (canopy) dominated by Melaleuca quinquenervia has the unique code 4003. A fifth digit identifies the crown cover in map polygons: 1 = mid-dense to dense (e.g. 40031 for M. quinquenervia open and closed forest); and 2 = very sparse to sparse (e.g. 40032 for M. quinquenervia open woodland and woodland).;; API groups are generally analogous to plant associations sensu Beadle (1981): 'a community in which the dominant stratum exhibits uniform floristic composition, the community usually exhibiting uniform structure'. In rainforests, however, floristic composition of the tallest stratum is often somewhat variable within and between stands. Where this is found to be the case, an API group is assigned to the most appropriate suballiance of Floyd (1990). Sun et al. (1997) compare this system of vegetation classification and mapping (as 'NSW NPWS Coastal Vegetation Mapping') with systems in use for other parts of NSW and Australia.; ; Legends for maps; ; A legend facilitates the interpretation of each project map by describing the structure and floristic composition of every API group. The API groups are named after dominant indicator species, usually for the tallest stratum although occasionally dominant species of a second (mid) stratum are also considered. The general range in height and crown cover for each API group is expressed using the structural classes of Walker and Hopkins (1984), for example Banksia integrifolia subsp. integrifolia mid-high open woodland and woodland. As observed during fieldwork to validate the API and vegetation mapping, subsidiary (10-30% of total crown cover) or minor (,10% of total cover) associates in the tallest stratum are given for each API group, along with any emergent species above the tallest stratum (generally ,5% of total crown cover). Also provided for each API group is a list of the more abundant species in lower strata or otherwise common as specialist growth forms (e.g. vines). Where applicable, the legend also lists the analogous Forest Type (Forestry Commission of NSW 1989) for each API group (e.g. API group 40021: Eucalyptus robusta open forest forms part of the broader Forest Type 30: Swamp Mahogany).;; Project output and applications; ; The vegetation mapping completed to date includes all large and many smaller conservation reserves from the Forster district northwards, in addition to areas of significant native vegetation on Crown or freehold land.; ; Future directions for project refinement and application; ; Due to mapping procedures used in the past, spatial inaccuracies are evident in the current coastal vegetation mapping data set when overlayed on more recent ortho-/satellite imagery. Attribution of polygons is considered to be relatively good, however advances in technology such as on-screen stereo capture software and digital stereo-/ortho-imagery has significantly improved interpretation and mapping accuracy.;; With the availability in 2009 of NSW Department of Lands ADS40 digital imagery (stereo- and ortho-) and with some of the original mapping and fieldwork having been completed 25 years earlier, a revision of the coastal vegetation mapping project series is timely and would provide:;; \* refinement of polygon attribution and boundaries;; \* spatial accuracy commensurate with ADS40 ortho-imagery; ; \* a temporal context for many projects, particularly for coastal headlands where vegetation change has been mapped over a time series beginning in the 1940s (Dodkin et al. 2007); ; \* not only API group and cover code attribution for each polygon, but extended to include an API confidence score, an understorey code, and attribution to landform and landscape categories (e.g. soil landscape process group, landform element);; \* a single unified, spatially and floristically consistent GIS layer to portray plant biogeography and habitat preference across a wide range of coastal and near-coastal landscapes in northern NSW;; \* a mapping and classification

system that accommodates future mapping projects in hitherto unmapped parts of coastal NSW .; ; References; ; Beadle, N.C.W. (1981) The vegetation of Australia.
